Introduction: The Evolving Role of Vascular Interventional Radiology

Vascular interventional radiology is a subspecialty that employs minimally invasive, image-guided techniques to diagnose and treat vascular diseases. Over the past decade, VIR procedures have

gained prominence owing to their reduced morbidity, shorter hospital stays, and comparable or superior outcomes relative to traditional surgical interventions. The current evidence base underscores its utility across a spectrum of conditions—from peripheral arterial disease to cerebrovascular disorders—reshaping treatment paradigms and enhancing patient care.

The Foundations: Historical Perspective and Technological Advancements

Evolution of VIR Techniques

VIR's roots trace back to the advent of angiography in the early 20th century. The subsequent development of catheters, guidewires, and advanced imaging modalities—such as digital subtraction angiography—paved the way for minimally invasive procedures. Recent technological innovations include:

- High-resolution imaging systems enabling precise localization.
- Drug-eluting balloons and stents improving patency rates.
- Embolic agents tailored for specific indications.
- 3D imaging and fusion techniques for better procedural planning.

These advancements have significantly expanded the scope and efficacy of VIR, making it a cornerstone in vascular therapeutics.

Evidence Supporting Technological Progress

Multiple studies have demonstrated that newer devices and imaging techniques improve technical success rates and reduce complications. For example, randomized trials comparing drug-eluting stents versus bare-metal stents in peripheral artery disease show enhanced long-term patency with drug-eluting options, aligning with current guidelines.

Current Evidence in Specific Vascular Interventions

Peripheral Arterial Disease (PAD)

Epidemiology and Clinical Significance

PAD affects over 200 million people worldwide, often leading to limb ischemia and amputations. Traditional management included open bypass surgery; however, VIR techniques now offer less invasive alternatives.

Evidence Base

- Endovascular revascularization: Multiple randomized controlled trials (RCTs), such as the DURABILITY trial, support the efficacy of endovascular therapy in limb salvage, especially in patients with comorbidities or high surgical risk.
- Drug-coated balloons (DCBs): Meta-analyses indicate DCBs significantly reduce restenosis and target lesion revascularization compared to plain balloons.
- Stent technology: The use of covered stents and drug-eluting stents has shown promising results in complex lesions, with improved patency rates documented in recent studies.

Key takeaway: Current evidence supports endovascular interventions as first-line therapy for many PAD cases, with ongoing research aiming to optimize device selection and procedural strategies.

Cerebrovascular Interventions

Ischemic and Hemorrhagic Stroke Management

VIR plays a critical role in acute stroke management, especially in mechanical thrombectomy for large vessel occlusions.

Evidence Synthesis

- Mechanical thrombectomy: Landmark trials such as MR CLEAN, ESCAPE, and DAWN have established thrombectomy within 6-24 hours of symptom onset as standard care, significantly improving functional outcomes.
- Intracranial stenting: While stenting for intracranial atherosclerotic disease remains controversial, recent observational data suggest potential benefits in carefully selected patients, though more RCTs are underway.
- Embolization for hemorrhagic stroke: Embolization techniques, including coiling for aneurysms and arteriovenous malformations, have high success rates with low complication profiles, as evidenced by studies like the International Subarachnoid Aneurysm Trial (ISAT).

Implication: The robust evidence base underscores VIR's pivotal role in acute stroke care, with ongoing innovations aiming to expand indications and improve outcomes.

Venous Interventions

Deep Vein Thrombosis (DVT) and Pulmonary Embolism (PE)

Venous interventions, including catheter-directed thrombolysis (CDT) and pharmacomechanical thrombectomy, provide alternatives in cases resistant to anticoagulation.

Current Findings

- DVT: The ATTRACT trial, a large RCT, questioned the routine use of thrombolysis for DVT, showing limited benefit in post-thrombotic syndrome reduction but emphasizing select patient populations may benefit.
- PE: Catheter-based interventions have shown promise in massive or submassive PE, with studies indicating improved hemodynamics and reduced mortality, although high-quality evidence remains limited.

Summary: Evidence supports individualized decision-making, with VIR interventions offering significant benefits in selected cases, especially where anticoagulation alone is insufficient.

Evidence-Based Guidelines and Practice Patterns

Multiple organizations, including the Society of Interventional Radiology (SIR), American Heart Association (AHA), and European Society of Vascular Surgery (ESVS), have issued guidelines incorporating current evidence.

- Emphasis on patient selection based on clinical and imaging factors.
- Preference for minimally invasive approaches where evidence supports efficacy.
- Incorporation of new devices and techniques as evidence emerges, with a focus on safety and long-term outcomes.

Challenges and Controversies in Current Evidence

While VIR has demonstrated impressive progress, certain areas remain contentious:
